## ECE 417 --- ROBOTICS <br> Lab 4, Spring 2021

For this lab you will program the inverse kinematics for the Lab-Volt robot. Add the following routine to the ones developed previously.

Write a routine which will take a $4 \times 4$ homogeneous matrix as input and will output the required joint angles for the Lab-Volt robot. You may assume that the desired position and orientation is obtainable. Your routine should return the "elbow up" solution with $\theta_{3}$ positive. This routine should be tested as follows: input the 5 joint angles from the keyboard, use the forward kinematics routine of Lab \#3 to compute the transformation matrix, call the routine here to recompute the joint angles, then print the recomputed angles.
